Deploying the Chronic Care Model to Implement and Sustain Diabetes Self-management Training Programs

Purpose

The purpose of this project was to evaluate the utility of using the 6 elements of the chronic care model (CCM; health system, community, decision support, self-management support, clinical information systems, and delivery system design) to implement and financially sustain an effective diabetes self-management training (DSMT) program.

Methods

The University of Pittsburgh Medical Center (UPMC) uses all elements of the CCM. Partnerships were formed between UPMC and western Pennsylvanian community hospitals and practices; the American Diabetes Association DSMT recognition program provided decision support. A clinical data repository and reorganization of primary care practices aided in supporting DSMT. The following process and patient outcomes were measured: number of recognized programs, reimbursement, patient hemoglobin A1C levels, and the proportion of patients who received DSMT in primary care practices versus hospital-based programs.

Results

Using elements of the CCM, the researchers were able to gain administrative support; expand the number of recognized programs from 3 to 21; cover costs through increased reimbursement; reduce hemoglobin A1C levels; and improve patient outcomes.
els (P < .0001), and increase the proportion of patients receiving DSMT through delivery in primary care (26.4% suburban; 19.8% urban) versus hospital-based practices (8.3%; P < .0001).

Conclusions

The CCM serves as an effective model for implementing and sustaining DSMT programs.

Diabetes self-management training (DSMT) is widely considered to be an important part of diabetes management.1,2 One of the goals of the US Health and Human Services’ Healthy People 2010 is to increase the number of people who receive diabetes education from 40% (1998) to 60% (2010).3

The national standards for DSMT4 administered through the American Diabetes Association (ADA) recognition program5 provide a framework for delivery and quality. Medicare and other third-party payers reimburse for programs when they meet ADA requirements. Reimbursement is linked to codes, and charges are typically based on Medicare rates.6 Reimbursement is critical in generating revenue to support nurse and dietitian educators who provide DSMT. Educators can be the target of cost-cutting initiatives when financial stability cannot be demonstrated.7

The numbers of patients who receive diabetes education are disappointingly small.8,9 Access to education has been proposed as a barrier, particularly in communities in which the closest DSMT program may be miles away.10 Another potential problem may be the traditional way in which education is prescribed and delivered. Currently, physicians are expected to refer diabetes patients to a hospital-based DSMT program. This process is consistent with the current system of health care delivery as it applies to acute care where services are provided at a hospital. Although more than 90% of patients with diabetes are cared for by primary care physicians (PCPs),11 education is rarely available in the primary care office.1,2,13

Patients and physicians at University of Pittsburgh Medical Center (UPMC) identified education as a barrier to the promotion of quality diabetes care.10 In an effort to provide education for physician practices and outlying hospitals, the UPMC Endocrine Division supported a certified diabetes educator (CDE). This provided an immediate solution, but a long-term strategy was needed for the UPMC system.

In contrast to traditional methods, the chronic care model (CCM) provides a framework for a systematic approach and has been shown to improve processes and outcomes.4,14 The CCM is based on the premise that effective chronic disease programs are delivered in partnership with health systems and communities.14-16 Although the CCM has been used in diabetes improvement projects, it has never been tested in facilitating DSMT programs.10,17,19 The CCM identifies key elements that are critical to success: (1) health system, to serve as the foundation by providing structure and goals; (2) community, to link with community resources; (3) decision support, to ensure that providers have access to evidence-based guidelines; (4) self-management support, to help patients acquire skills and confidence to self-manage; (5) clinical information systems, to provide timely access to data about patients and patient populations using clinical information systems; and (6) delivery system design, to restructure medical practices to facilitate team care.

It was the objective of this study to evaluate the benefits of using all of the elements of the CCM to expand and support DSMT. The researchers hypothesized that introducing the components of the CCM would lead to increased administrative support along with improved reimbursement for services and A1C levels. By increasing the number of programs and providing DSMT in primary care, it was hoped that some of the barriers to DSMT could be curtailed, including access.

Methods

Setting

UPMC is an integrated health system that includes 19 hospitals and a physician division with 166 primary care and 1400 academic physicians providing services for approximately 90 000 people with diabetes in western Pennsylvania. Implementation of the CCM involved a stepped approach and changes at multiple levels from 2000 to 2004. This project was referred by the
University of Pittsburgh Institutional Review Board to the UPMC Quality Council, where it was approved as a quality improvement project.

The CCM implemented at UMPC is outlined in Table 1. The CCM differs from traditional approaches in that it emphasizes self-management support and training.14,15 The ADA recognition program provided the framework to implement the evidence-based DSMT standards5 and served as the decision support. In compliance with ADA requirements, an Advisory Committee was established and became responsible for developing an annual plan, assessing the target population, and determining methods for continuous quality improvement (CQI). The Advisory Committee realized a dual purpose could be served if reports on reimbursement, access to DSMT, and A1C levels were available. These reports would serve as important CQI measures and would give UPMC

administration the feedback necessary to gain continued support.

**Elements of the CCM**

In 2000, the UPMC health system designated diabetes as its quality initiative and agreed to administratively support implementation of the CCM in its network of community hospitals and practices.
received ADA recognition and therefore could not bill for services.

**Patient reach.** The proportion of patients who received DSMT at 1 urban and 1 suburban primary care practice was compared to the proportion who received DSMT at the 8 hospital-based programs where DSMT services were available during the same time period (July 2003-December 2004).

**Analyses.** The statistical analyses incorporated both descriptive and inferential techniques. Measures of central tendency (e.g., proportions, means, standard deviations, medians, etc) were used for all descriptive analyses. In univariate analyses, Student t tests for continuous data and Pearson’s χ² tests for categorical data were used to determine differences in means and proportions. In addition, for each outcome of interest, analysis of variance was used to test for differences in means between more than 2 groups, and χ² tests for trends were used to test for differences in proportions between more than 2 groups. To analyze the effect that education had on A1C values, a multilevel model for change was used. This type of analysis allows one to measure change over time while allowing the individuals to be their own controls. All models considered were adjusted for age.

**Results**

**Decision Support**

Between 2000 and 2004, the number of ADA-recognized programs grew from 3 to 21 including pediatric, rural, academic, and 2 primary care practices.

**Clinical Information Systems**

MARS afforded the opportunity to track reimbursement and A1C levels. As shown in Figure 2, at the 8 DSMT hospital programs where revenue was captured, total charges in 6-month intervals increased from the beginning of the tracking period in January 2002 from $120,846.00 to $241,472.00 in June 2004. Total payment per 6 months increased from $37,192.00 to $120,572.00 over the same period. Interestingly, efficiency of collection increased from approximately 25% to 50%. Most important, diabetes educator effort was covered by the third 6-month period. Thus, at the initiation of this project, DSMT services were a loss leader. In contrast, by the conclusion, educators were more than self-supporting their efforts devoted to DSMT.

When examining patient data from the hospital programs, the mean age was 57.2 years. Patients who received DSMT at the point of service in a suburban office were significantly older than those at the urban PCP office (age: suburban = 66.2 years vs urban = 54.7 years, P < .0001). Patients entered the hospital DSMT programs with higher mean A1C values did those in the primary care practices (8.28% vs 7.83%). Figure 3 shows the analysis of the A1C values through 1 year after the initial education session. A mean age-adjusted decrease in A1C values in those in hospital programs (0.95%) versus primary care (0.48%) was achieved (P = .0001). A longer follow-up period would be necessary to determine the effects of DSMT over time.

**Delivery System Design**

In tracking numbers of patients who received DSMT from July 2003 through December 2004, it was found that a 2- to 3-fold greater proportion of patients were reached when DSMT was made available in PCP offices.
(26.4% suburban; 19.8% urban) as compared to 8.3% of the population who were referred to hospital-based programs. Of 31,000 patients identified as having diabetes in MARS, only 13% (4190) received DSMT at hospital-based programs during the time period. Of 1306 identified diabetes patients in both the suburban and urban practices combined, 24.7% received DSMT in their PCP’s office.

**Discussion**

In this report, it is demonstrated that the CCM is an effective framework to support DSMT, results in improved program and patient outcomes, and is fiscally self-supporting. With reliable clinical information systems, educators were able to demonstrate the benefits of DSMT delivered in different settings on A1C levels. In a fiscal environment in which hospital administrators are skeptical of services that do not generate revenue, tracking reimbursement in justifying positions was also important.

While the ADA recognition process is widely accepted, there is a paucity of literature on the delivery process, reimbursement practices, and, most important, hard outcomes. Educators in both the ADA and the American Association of Diabetes Educators (AADE) report program closings and express frustration with the implementation of Medicare benefits and receiving appropriate reimbursement. The AADE and ADA collaborated to conduct a survey of DSMT programs. Their findings in 122 sites confirmed the findings of other studies that indicate that diabetes education is an underutilized service. Nearly half of the sites reported an average visit volume of fewer than 50 visits per month, and 19% reported only 51 to 100 visits per month. More disappointing were the reimbursement practices. Of the sites that bill Medicare, only 57% were collecting the mandated collection fees, while 37% of the respondents did not even know how often they were collecting these fees. Despite attempts to remedy this problem, only 57% reported having a fiscal reporting system. The ADA and AADE concluded that processes for monitoring billing and establishing a reporting system specific to DSMT were critically important.

The authors took this message seriously and created a system to explore and satisfy these recommendations. Through the repository, educators had the opportunity to monitor reimbursement. UPMC education and billing staff members collaborated and reviewed monthly reports to determine payment practices. Although Pennsylvania mandates coverage for education, compensation for services was not always provided. As reported by others, in addition to external reimbursement difficulties, numerous internal problems were identified throughout the system that precluded reimbursement. Education charges based on Health Care Common Procedure Coding System codes were inaccurately entered, recognition certificates were missing, and charge-entry staff neglected to enter charges. Once these problems were identified, internal efforts to correct the problems and capture reimbursement were implemented.

The authors were also eager to increase their DSMT services and realized that they needed to improve access. An important innovation was that they went beyond traditional models of DSMT delivery as a result of their system redesign; by integrating educators directly into offices, access to DSMT increased. It was demonstrated that DSMT delivered in the office has a positive effect on A1C levels along with PCPs and educators reporting other advantages that included increased communication.
on management plans and CDE involvement in medication initiation and adjustments. Patients reported greater comfort with location and easy access to the educator for questions and problem solving. The intent is not to suggest that hospital-based programs be replaced or eliminated but that opportunities to support education and follow up in other settings are investigated.

To the best of the authors’ knowledge, this project is the first to systematically develop a DSMT network using all of the elements of the model and report on ADA recognition and reimbursement practices. The CCM has been tested and shown to improve outcomes. However, much of the research has focused on specific components of the CCM model, and evaluations of an overall plan are less frequent. More recently, Wagner et al performed a survey and site visits of 72 chronic disease management programs that were considered to be innovative and effective. Only 1 program had instituted all 6 components of the model.

The limitations of the project are recognized. The UPMC diabetes initiative is in its infancy. As the project evolves, each of the components of the CCM continues to be developed and refined. For example, not all of the DSMT programs were linked to the data repository during the initiative.

Another weakness is that the researchers were unable to effectively track all hemoglobin A1C levels throughout the project. Patients may have had laboratory tests done elsewhere. It is recognized that factors other than DSMT may have influenced improvements in glycemic control and that A1C levels are not the only indicator for quality. Other medical interventions and outcomes must be controlled for and captured in future studies.

It is recognized that reimbursement needs to increase to fully support an educator’s salary. Now that billing practices have been remedied and new avenues for access have been identified, UPMC will move more educators into primary care practices, increase group visits, and begin an aggressive DSMT promotional campaign in its communities.

Although this study was performed in a large health system with access to many resources, it serves as a model for others to explore creative solutions. It provides a template for educators to explore collaboration with heretofore unlikely partners in administration, finance, and information systems and to create opportunities outside of traditional roles, such as the development of business models for sustainability. Smaller and independent facilities may seek opportunities to share data systems or form consortia to organize systemwide recognition applications. Hospital-based educators could partner with primary care practices to provide follow-up education in an office and seek creative methods for billing for services. Innovative technological methods, virtual teams, and community-based education afford other exciting opportunities that need to be tested. First and foremost, educators and physicians need to be open-minded to consider areas for change.

Developing systems that promote accessible, sustainable DSMT programs that affect metabolic outcomes have large-scale public health implications. Organizing efforts to support the facilitation of DSMT is critical in meeting the Healthy People 2010 education objectives.
